Cor,

That is a great view on the whole situation, and I 100% agree.

HTML it is – that at least i have a pretty good base from my notepad days.

Thanks,

Miro

Miro,

ASPNet has to use HTML as that is used by all the webbrowsers. If Microsoft would build something that was independend from that, then they would most possible get a fine from governement parts in the US and the EU because they are then inventive, while others complain while doing nothing about invention because they will make money with their not so inventive products.

A little bit as it was in the middle ages of Europe where at a certain moment progress was completely stopped and in fact was going backwards. (Only the rich people were profiting by that because they made most people slave)

This means that we still have to use the way it was from the beginning of Netscape in HTML
<table><tr><td> to do things like what you want.

I think i found it,

after draggin the object to the form, I click on "Format" and then "Position"

Is there a default somewhere to set it to absolute always?
Or whats the norm people have set ? – If there is one.

Sorry for the begginer question, last 2 chapters are in ASP.net and its a first time for me in this editor.

In my book the book drags a datagridview and a
detailsdatagrid onto the form,

The person is able to set the two grids side by side.

In mine – i can only seem to set them under eachother.

Its almost like I am missing something like an 'absolute
location' parameter or something like frontpage had to drag
items on the form.

Have I missed setting a parameter?

thanks,

Miro
