I have a project that uses an add in to deliver most of the functionality. This included a proprietary save in which I store data on the sheet for the next time.

A request was made to be able to "minimise" the form to look at the sheet. I put this in but this then exposed a method by which the user can save using excels save not using the forms methods that store vital data before the user exits.

To catch this I need to put a workbook_beforesave() event in to the worksheet itself to call a function in the addin to do the stores as if the user had used the form save.

I have used code from <http://www.cpearson.com/excel/vbe.htm> but when I compile/run I get variable not defined errors on the "vbext_pk_Proc"

```
Function ProcedureExists(ProcedureName As String, ModuleName As String) As Boolean
On Error Resume Next
If ModuleExists(ModuleName) = True Then
ProcedureExists = ThisWorkbook.VBProject.VBComponents(ModuleName) _
.CodeModule.ProcStartLine(ProcedureName, vbext_pk_Proc) <> 0
End If
End Function
```

I tried Dim vbext_pk_Proc as ProcKind, but then I just got a user defined type error

Looking in my object browser I don't seem to have the vbext_<> set of declarations but I can't figure how to reference it.

Help!!!
