Hi, not sure about documentation, and I can't remember how I latched on to my first example, but I did a search on Google, for example you could use oConn.Open as your search term, although I didn't know anything like that at the time.

The custom function only does one process per function, so I've created a number of functions all using different SQL statements to return different things. They all need different parameters.

They are however all in the one XLA file.

Regards
Mike
