Hello,

We get a lot of bounces from a particular domain that we send to a lot: "554 5.6.1 Body type not supported by Remote Host". I understand it's because the remote domain apparently doesn't support 8bitmime. If I stop our Ex2k3 server from advertising 8bitmime according to MS Q257569, does that mean that it will generate the same errors when another email server or clients try to send in that format? Under what conditions do clients send in 8bitmime? The latest incident was sent to a large list with a .doc attached.

Thanks,
Matt
