HI ED

thanks for that

I have run nslookup on the domain name and seems ok
I have compared the results with the domain name that is working and the are exactly the same result.
Here is a thing when I orginally registered the web that is not working as an existing domain name but new web host I may have left of the www. when entering the domain name does that effect it, because if I run the nslookup with www. and I get a different result in the cmd line. Also there seems to be problem with reverse dns could that be a problem? Although it is working with others on the same web host as you know.

One other thing the mx record on the entry place is just the domain name without the www. (domain.com) and not mail.domain.com . Is that OK? I have changed one them that is working to see if effected the mail delivery.... and it was ok.(not yet on the the the one that is not working) but when I run cmd line nslookup before I changed I got 'mail exchanger' mail.domain.com . Could that have some effect. ?

Also the network/web host, I did a check and mentioned some about an open dns system or server.

The only thing is that the email server that is giving the problem just happens to one of the biggest banks in the world! hey may have a lot of security and may not like some messing around their neck of the woods,,! Have you had anything like this before? Seems pretty wierd.

Appreciate the help,
the only solution right now is that I transfer the domain hosting to the webhost – if that will fix it?

thanks again
regards

Russell
