On a 50 GB partition, it currently has about 19 GB free. When the server stops accepting emails, I have nothing new in the event viewer. I do get a couple 0x6bb errors about deleting restricted views, but have read that I can ignore these.

The last time it ran an online defrag, it reported that my limit was 30GB and the current physical size of the database (edb file and stm file) is 26 GB.

My public folder store is limited to 18 GB, but the current size is < 1 GB.

I thought it would be log files, but then my hard drive should be full. The server has three partitions but none is even close to full and all log files are on the same partition as the database. Unless there is another limit I am unaware of? But the Exchange database and hard drives seem to have space...

how much free space? this definitely sounds like a space issue...nothing in the event logs? sounds to me like a drive that contains some processing or transaction logs is filling up...do you have any protocol logging turned up, or anything like that?

I have an Exchange 2003 server that works well for weeks, and then will refuse incoming mail without any warning. It still allows internal mail, it does not dismount the inf store, it leaves nothing in the event log, it still

Re: Incoming mail stops..

sends mail out OK. Typically it will start running after I backup the Information Store.

So many of you may think it is a size limitation, but the hard drive has free space and the event viewer says that after an online defrag that night the store still had 5 gig free. (I bumped up the limit to 30 gb, the store hovers around 25/ 26).

Any ideas where I could start? With no warning and backups taking 5 hours, it is not making anyone happy. By the way, I do have scheduled backups that flush the logs every weekend...

Thanks in advance.
