You don't need a wildcard cert, but you do either need a SAN (subject alternate name) cert with multiple names on it, or you need to set up another IIS virtual server and use a normal cert with the autodiscover name.

"markm75" <[markm75c@xxxxxxx](mailto:markm75c@xxxxxxx)> wrote in message

I registered discover.domain.com on our public dns, so that OAB functionality would work with rpc over http clients.. its working fine, except that users get a certificate warning about a mismatch on the name on the ssl..

I have no interest at this point in getting a wildcard ssl certificate.. but basically just want it to work..

Is there a command i'm sposed to run in the shell to fix this?

The basic warning is something like discover.domain.com doesnt match wan1.domain.com.

Anyone fixed this without getting a wildcard ssl?

Thanks much..
