Email from exchange in site 1 gets to exchange in site 2 using smtp. This assumes both exchange servers are in same Routing Group and have connectivity to each other.

The other option is to create a separate Routing Group for site 2 and move the Site 2 exchange server to that RG. Connect both routing groups with a Routing Group Connector. You typically do this if there isn't enough bandwidth between 2 sites – you can control the message flow over a Connector – schedule message transfer, decide who can send/not send... this also requires both sites can communicate with each other.
