I'm developing a class that accesses the Exchange Store via WebDAV and do some common operations (send/read mail, create/read/modify tasks and appointments, etc...).

I'm testing it via an ASP.NET application with integrated windows authentication and impersonation turned on. The network context the application is running in is properly set for delegation (with Kerberos authentication).

Everything is working fine, except for creating new items in the Calendar folder...

I found that the problem is that the Calendar folder is the only one with authorizations restrictions: the default user have reviser rights. If I set Calendar authorizations like other folders authorizations it will work, but i cannot change this setting permanently due to my company policies. I tried do set owner rights to my user, but with no results...

The only time I have created a new appointment successfully was the very first time I started the ASP.NET application...

Any idea?
