Hi all,

I found the solution for this. This can be configured in our WSDL files.

Here is what you guys will have to do,

1.. Locate the area where your method is described in the WSDL file. If your method is MyMethod you will get 2 method descriptions for the Request and the Response. The names would be,

1.. Mymethod

2.. MyMethodResponse

2.. Against the MyMethodResponse all parameters returned will be listed. This list will contain all parameters from the Mymethod and an additional parameter with the name Result. Excluding Result parameter delete all other parameters.

3.. Search your method further down and you will find areas the operations are described. This tag will start as Operation and the name attribute will contain your method name.

Ex: <operation name='MyMethod'>

4.. This will contain 2 sub levels Input and Output. You will have to change the details of the Output tag. All the parameters will be described against the Part attribute in this tag. Excluding Result remove all other parameter names.

5.. Now your method will return only the return value of called method not the parameters passed to the Request.

Like this way you guys can control the values returned in the SOAP response.

Please note I'm using VFP XML web services publisher to generate all these WSDL files using my COM+ application.

Hope this will help.

Best regards,  
Nadee

Hi all,

After analyzing WSDL files identified that for the description of the  
Response all the parameters of the Request are described with the

additional

parameter "Result". This "Result" will contain the return value from the  
called method and the other parameters will contain the values available  
when returning. So if we don't make any change in the called method the  
parameters will be returned as it is to the client side.

Is there a way to restrict these parameters returned from the server?

Any help is greatly appreciated.
