Hi!

In ISA 2006 how often data is synchronized by default between two Configuration Servers where one is set as replica of another?

If there are two ISA Arrays should all members of both of them be added to eg. enterprise management computers to have administrative access from console on one array node to members of second array? Or is it somehow managed by system policies?

What ports should be opened between ISA Array and Configuration Servers?

If second ISA Array is made of one node and on that server there is also configuration server deployed and I set that server as alternate configuration server for first ISA Array should I add both nodes of this array to eg. Managed ISA Server Computers on the second array?

Regards
Silmar
