No,
What you have described is suitable only if you want to support anonymous users on specific machines with assigned IP addresses.

If your goal is to manage Internet access based on Windows logon no matter what machine the User may use, you should not reference client sets, you should reference a Windows security group which contains your Windows User accounts.

Make sure that a matching Protocol rule is created which also references your Windows security group and your Users will be granted access.

Lastly, doublecheck you don't have a Default rule that permits all Users access to everywhere (Either or both Site & Content and Protocol rules).
