Hi Dan,

First of all the logical directory security (IIS):

If only authenticated visitors may enter, clear the "anonymous access" box and choose you're authentication:

→ Basic, Digest or Integrated authentication.

Basic isn't really secure 'cause it 'll send the password in clear text.

If you want that visitors who are already authenticated (logged on) on you're network (AD) "Integrated Security" is the best. This way these visitors don't need to authenticated themself again.

If they're not already authenticated they will be asked to authenticate themself.

The physical directory security (fs):

See that the IUSR_XXXX and everyone is cleared from the permissions. Then just add the groups (/users) you want to give permission.

Greets,

...Tim.
