Hi all,

sorry, not sure which group this belongs too...

I have a Win2k server running IIS on an Intranet. All clients are win2k using IE.

My site uses a database for username authentication. On authentication the user's ID number is used as session variable. This is checked from page to page for authentication.

Problem is some client machines see the session variable and some dont. Access to the pages depends on seeing the session variable.

Why does it work on some machines and not others? I am stumped and do not know what to do. Anyone have any ideas?

Cheers, Bill.
