Hi all,

-Scenario: 2 forests, 2 way trust, PKI in both. IAS Forwarding setup correctly and working when statically entering the complete host name of computer and forwards accordingly as designed.

I need to know the correct pattern matching syntax to identify "ANY" computer jumping on the switch and getting sent to the correct IAS server via a forwarding rule. A little confused from the doco and can't seem to find any "host/" examples but rather user authentication examples.

The attribute comes in as "user-name = host/COMPUTERNAME.domain.local"

I have two forests and need to be able to distinguish between the two and forward accordingly. I just need the correct syntax.

"host/" will not change, nor will "domain.local". What will change is just the computer name...

Thanks in advance!

-Greg
