Hi,

i've written an addin in C# for Word (2 Buttons on a Toolbar) and it works fine when installed with the created setup on Machines having Visual Studio .net installed.

On Machines having only the .net Framework (redistributable) installed, the plugin isn't loaded.

First I tried to include the office.dll in the setup project. The plugin loads but the function called by a button, trying to access the active document, doesn't work. The other button that open's a form and saves information in the registry works fine.

Then I tried to exclude office.dll and include the Microsoft Office XP PIA -Dlls in the setup, with the effect that the plugin even doesn't load anymore.

Why are the Office-Pias only available for Office XP and 2003? What can be done with Office 2k?

What do I exactly have to do to distribute a Microsoft Office Shared Add-In? It would be cool if you can give me a step by step example, because I'm not very familiar with windows programming.

Thanks a lot

Hendrik
