We have a nice Access 2000 database, residing on a nice fast server, used by six users on Windows 2000 and Windows XP workstations. About twice a day we get the error "Could not update currently locked", and the only fix is for everyone to exit from the database; then we can restart it and it works OK.

The users haven't been able to spot any trends or offer any clues about when or why it happens.

Can anyone offer any suggestions about what might be causing this, or how I can go about troubleshooting it? Thanks!
