We are volunteers here who get to choose who we help and to what degree. If you want better support than you get here, go pay for it. You are guaranteed to turn off potential respondents with posts like yours in <http://snipurl.com/bho5>. We don't work for you. We are not employed nor paid to be here. Some problems are so new that no one in the public community has a fix yet. However, the update has been available since November 10, there are few posts found in Google Groups regarding "ixfAssemblyCopy", so it is likely something peculiar to your setup (and why the other poster asked you to divulge your setup to see what might be common with them who is having the same problem).

When posting, get used to the "me too" replies. They add nothing to the content of the thread and are distracting fluff added by those that cannot resist chiming in when they suffer the same ailment. They don't know how to use the Watch flag in their newsreader or they are using a webnews-for-dummies interface, so they track on their me-too reply by their name (i.e., search on it) so they can search for the old thread by their name rather than just watching those of interest to them.

Since you are asking about problems with *installing* an update then it

is not a problem specific to Outlook (which may not even be running when you do the Office update). It doesn't seem to be an Outlook problem at all; see <http://snipurl.com/bhop> (found by a Google search on "ixfAssemblyCopy" that you could've done yourself rather than complain that no one choose to address your problem here). Rather than edit the boot.ini file to see if the suggested fix works for you, just right-click on My Computer, Properties, Advanced, Performance, DEP tab – which is new to WinXP SP-2. However, I found a post mentioning "Error 2902" at <http://snipurl.com/bhp4> (another Google search) which is dated back in 2002, so maybe it is a .NET problem. Did you do a recent Windows Update to ensure you have the latest .NET updates?

If the problem is critical – and you don't want a better Bayesian filter than provided in OL2003, like SpamBayes or SpamPal (with its Bayesian plug-in) – you might end up having to pay Microsoft to fix the problem assuming they know what's wrong. Have you yet tried rebooting in clean mode by using msconfig to eliminate startup programs and then try installing the update? Can you download the update and reboot into Safe mode to see if it works there?
