Hi,

i'm a trainee and have become an exercise.

I have to check if our desktop deployment could be made easier and flexible.

Today we install out desktops with the SMS2003, there are several packages wich are used, although different applications like adobe acrobat reader / writer.

There are two ways of deployment, one is the standard image and the user requests additional applications, the other is to use a bootcd (probably pxe), there can be the os and the applications / languages selected.

Is there a way, to let the user choice of the wanted / needed applications and OS through a webpage. The webpage generates a individual "unattended" file, this file will be placed on a usb stick conncted to the new pc. The pc reboots with pxe boot and gets the deployment as selected.

So i need a few hints if this could be a possible way. It is for a presentation / report, so i don't need a fully lighted way to a implementation.

Thanks for your help,

Gregor
