Andrew:

Well I recreated the login but it didn't make any difference. The form that didn't work before still doesn't work and the forms that did work before still work. Any other suggestions ?

Randy

You might have lost the relationship of the Login to the user in the db. It may be able to connect but not get to the db itself. Try dropping the login and readding it making sure to specify the database access when you do.

I am using "Integrated Security=SSPI;" (Windows login info) in all of the connection strings used in the various forms. Will it still be necessary to do something with sp\_change\_users\_login ?

Did you resync the logins to the users in that db after you attached it?  
If not check out sp\_change\_users\_login in BooksOnLine.

I have a C# client application that uses SQL Server as a backend. It works fine on my development workstation. But when I moved it to another test workstation four out of the five winforms worked fine but one doesn't. The one that doesn't can open the connection and return the server version as a test of whether the open worked right. I does. But when you run the oledbadapter.fill command to fill the dataset it fails. It acts as if it can't open the server. Further reading shows that the fill command can actually open a connection on its own if necessary without the open command. Is there anything in the environment or SQL Server that could be causing this rejection. The SQL Server database was detached, copied, and then reattached on the test workstation. SO it should be a duplicate.
