I have a task that I want to use a combination of ADO recordsets and TSQL. How do I, for instance perform a count query, and do some functionality based on the the result. Ideally I would like to do a count e.g. `SELECT COUNT(idfield) FROM TABLE` into a variable and then do some ActiveX functionality based on the result rather than have to create a recordset from the query and then pull it into variable. Basically I want to know if you can combine TSQL and VBScript more easily than on a webpage. Regards, Chris.
