Hi everyone

How can I search database records in table1 such that the query returns the matched records and their percentages to which they are alike.

Actually the site administrator wants a search facility such that whenever he wants to register a new customer, fill out the whole registration form and than before saving the record, system searches the whole database against the provided form data. If a similar record is found against the new customer, system should display it with a similarity percentage. On the basis of this similarity percentage, administrator decides to save it as a new record or use the previous one.

Can anyone help in this regard. Any code will help alot.

Regards
