Why store the value at all? Is it that expensive to calculate? Could you cache it in your web server's memory instead of relying on SQL Server?

If you absolutely must store it in the database, perhaps you should consider using a table that stores rows on a per-user rather than per-application basis?

So instead of:

Orders

ProductId Quantity

You could have:

Orders

UserId ProductId Quantity

This would help ensure that users don't collide with each other.
