"permissions issues" is a pretty broad question any more details as to what types of things are executing? select? updates? drops?

if using windows authentication you just need to look at the users and roles and set these up manually.

by default sql will allow local admins on the box to have dbo priveledges on the sql server (you might want to remove this local admin group) but the easiest way to make the permission errors go away is to add the user causing the failure to the windows administrators group. but this of course makes the user an admin on the entire box so be careful.
