Hi,

I'm a web developer who is trying to expand my database knowledge by learning SQL Server 2000 (I've used Access previously) for creating dynamic web pages. I have two computers, both running Windows XP Pro SP2 that are networked together through a Netgear wireless router although these two desktop computers are connected to the router through ethernet cables, not wireless. On one system I have IIS running, as well as the software I use on a regular basis, including Dreamweaver MX2004. On the other computer I've kept it bare bones and am trying to install SQL Server 2000. I've installed SQL Server with logon set as Local System Account. I should mention that I don't currently have Windows passwords set up for either machine (blank) and I have Admin privileges on both. I have not installed Service Pack 3a yet although I have the cd for that. I'm able to get SQL Server to start when I start the computer and I can create ODBC connections on the machine it's running on. What I want to do and I am unable to do is create an ODBC connection from the other computer to the SQL Server computer. I'm assume it's a log in and permissions thing but I'm a little lost. Does anyone have any good resources that address something like this step by step or does anyone have any advice for doing this? I forgot to mention that I'm using SQL Server 2000 Developer's Edition. Thank you very much!

Mark
