Hi all,

Quick question. At my current job, we are looking to install an Access frontend that connects to our main database. This would involve everyone using the front-end to access the main SQL Server using a read-only user account. The only concern is how this will affect performance.

Is there any quick way to profile and monitor if this is creating a big drain on the database or if there is any problem in doing it this way?

Thanks a lot.
Iain
