Hi

Can anybody help me out with a problem? Is it possible to have a table which has other tables as entries? For example, suppose the main table is called table1. It contains two fields, a primary key field and another which contains tables. The tables in these fields, also only have two fields BUT the difference is that they will have a different number of rows.

Maybe this will give a better idea of what I mean:

ID tables

== =====

0 tableA
1 tableB
2 tableC

tableA has 5 rows
tableB has 2 rows
tableC has 20 rows

Does anybody have an idea of how to do this sort of thing?

Geoff
