Hello!

I have been assigned to a small project which implements a program that imports data from other applications to our DB (Access).

Some data are \*.dbf so no problem.

But some are custom binary files that I need to parse.

Users will select rows to import.

Is there are way that I can bind the data from a custom file to ADO so that I can show the data in a data-bound datagrid without saving the data into a database?

Similarly, it there a way to bind an array of structures to db-control? (Basically this is the same question as the first one, I guess).

Thanks in advance.

Sam
