John,  
There's no point in asking me - try it

Argusy,  
Thanks for the reply. The example I gave was not the whole thing. In fact MYFIELD in the db is a numeric key field. So '123' is record with key 123.  
I do understand why the movenext won't work, now.  
So the solution you gave, can it be used for keyed fields too or is there another way?

Your database has only one record with '123' in MYFIELD  
That's why opening the database then opening a recordset query works.  
The movenext also works because it is moving to the end-of-file marker of the created recordset  
Note I wrote --marker---.  
The end-of-file is actually a dummy or false record, but with no data.  
That's why the failure - it's now NOT a current record (it's beyond the EOF marker)

I'm making a couple of assumptions

## Re: Need some help with MOVENEXT/MOVEPREVIOUS

It's an access database  
you want the recordset to start with MYFIELD at '123'  
you want the remainder of the table.  
In that case, your query should be "SELECT \* WHERE MYFIELD => '123'".

Since your query DOES extract one record, MYFIELD's type is a string.  
Open your database in access and do a sort on MYFIELD.  
See how the numbers are sorted  
Then you'll see why you should be careful when using a string field to  
store numbers, and what you may get in a recordset mightn't be what you  
have expected

Also go to the last (blank) "record".  
It's not a record until you put something into any field. Once you do,  
another "record" is created on the next line. That should also give  
you a clue as to why you're getting the error message

I'm not going to ask you why are you transferring the data to another table  
That's like opening Pandora's box

John wrote:

Hi,  
I'm building an application, using DAO  
with VB6 (sp6) and I encountered the  
following problem:  
I open a recordset (rs), select a record  
by using e.g. SELECT \* WHERE  
MYFIELD="123".(placed in a string)  
This works, I get the record. (db  
contains 640 records, the select  
retrieves the third record) I use a  
routine that places all the fields into a  
table recordtype. Doing the select and  
the routine, the table is filled with the  
requested record.

## Re: Need some help with MOVENEXT/MOVEPREVIOUS

Thereafter I do a rs.MoveNext and I try to retrieve the fields, but than the error that there is no current record occurs.

So, the sequence is:

- 1) open db and recordset
  - 2) select the record by using a search argument (lets say to set a certain starting point)
  - 3) than a movenext to obtain the next record
  - 4) using the record fields by placing them in a table
  - 5) close the rs and db
- 1 and 2 works fine  
3 seems to work, no error occurs  
4 gives the error: No current record abort of the routine

Can anyone help me, please?

Regards,  
John
