Yeah, i got an idea like that too..but how the coding?

let me explain a little bit...actually, my application make the user compulsory to log in. So, my idea is, when the user have a batch of file that contains many files, they have to choose which folder database they want to put-in the data. Is it confusing? so sorry...

When we execute the application, the first screen should be a form where a user can select the database folder and then, the application will use it as the connection string to connect to the selected database. For information, the contain of each database folder is same. Example, if we have password table, user profile table, code table and so on, it will be inside all the database folder. The different is only the data put-in it.

many thanks in advance..kindly, provide me sample code...
