I have a VB control that is calling into a VC DLL and I need to debug the interaction between the two of them. I can start VB, start the program and attach VC to VB and it breaks in the VC DLL with no problem. At the same time, VB can tract through its own code in the normal fashion. A couple of days ago for no reason that I can think of, I could see back into the VB call stack and even trace through the VB code from within VC. This was **great** but I have not been able to duplicate that set up again. Was I delusional or is there some way to set things up so that VC can see into the VB stack?
