I am working on a security system software in VB.Net, while dealing in database I am facing several problems as follows:

1- in table there is a field for date and time, but in grid only date is shown, where i want to display the time only ( i am using ultra grid tool of infragestrics),,

2- Using selection formula for report (user may give 1,2,3 .. or more criteria for report)

3- using "views" in report

4- Adding serial key and a counter while making setup so that it may cover the piracy.

(counter may count the number of installation. After specific number of installation setup get expired.)

5- creating backup of database on user defined location in hard disk.

6- can we replace a cell value in grid

e.g i have field "user\_gender" of data type int where 1 means male and 0 means female. i did not make parent table for "gender", because there is only 2 possible records in table. i am assuming 1 and 0 as male and female. i need; when data is retrieved from database all 0's must be replaced with "Female" and all 1's must be replaced with "Male". One solution is this; that we use counter loop and set the value of user\_gender" field in dataset explicitly by checking "user\_gender" field. Is there any other solution..?

.
