Hi all,

I'm running out of controls on my main form (form1). So I've devised a plan to store the controls in another form(form2), and have it's contents loaded on the main form when required, then release it from memory afterwards.

The main form has frame1, which I plan to copy the contents of form2 onto it.

Form2, has a frame which has several other components on top of it.

This is my code

```
-----  
Dim f As Form2.Frame1  
Set f = New Form2.Frame1  
f.Parent = Form1.Frame1  
-----
```

How can I get it to work they way I want it to, without building an ocx?

thanks

Astro
