You can, you just need to make sure the client is binding to a different port then the server, (In case they are both running on the same machine).

Thank you very much for your help :-)

Actually, while thinking it through... chances are most of our customers use DHCP, with no static binding with hosts' MAC address, so that clients will have to use broadcasting to locate the server every time.

So... a better solution would probably be to display the Network Neighborhood and ask users to click on the name of the host that is acting as server, and remember this hostname. If IP's can change every time a computer is rebooted, its Netbios/hostname name won't.

Thanks again to both of you.
