Hi

I have a 1D array, populated with a list of values extracted from a SQL database.

I would like to be able to report on the number of unique values in the column together with a count of each of these values.

Can't seem to find out how to extract the data in this way – can anyone help me out, please?

You pretty much have to go through the list and count them up. Any "magic" way of doing it would just be doing that for you. If you want the database to do it for you, you can do "Select ValueField, Count(*) As ValueCount From TheTable Group By ValueField". To do it yourself, make an array to hold the unique values, and another to hold the counts. Go through the main list, check if each value is in the unique list, add it if it is not, or increment its count if it is.
