

Identifying computers running given program ?

We have program "A" that is loaded from a Windows Server by user from numerous locations remotely.

Many of the computers are left running 24/7 without terminating program "A".

What I would like to do is write a program that could identify these computers and then terminate the execution of program "A".

I am looking for a solution that does NOT involve having users of program "A" sign in and recording their presence, rather would interrogate the system in a network wide process.

Is this possible ? Any suggestions would be appreciated.

Duke
