Im currently refactoring an MFC application to an MFC DLL.  
What reasons would stop regsvr32 registering the DLL?

It gives the following hint

"Please ensure you have the appropriate permissions to modify the registry."

Which I can assure you I do have.

My hunch is it is something to do with some global data that may be being created etc – which was fine in an exe but now not in a DLL ?

Are there some definite do's/dont's when using a DLL vs an EXE ?

Has anybody had this type of problem before?

Im just having to eliminate lots of code to try and find the culprit?

It would appear problem is the permissions. Typically regsvr32 will fail because all the dependent dlls of that module being registered are not found. You can use Depends.exe on that module and see if you have all the dependent DLLs.
