When looking at this problem in the past, it's been because the netlogon process is up and running before the DNS server is. Thus, forcing a service to depend on another forces it to wait for other services to start.

In my example, I chose w32time because it's one of the last services to load.

Services load sequentially. And, if you were to think about it, on single-processor systems everything does. The OS just makes it look like things are happening simultaneously ;-)

Paul, what causes this to happen ? Isn't that all the services will be loaded sequentially one b4 another ?

Rgds

Daniel
