I think what happened, he made the change before AD replicated, so when he made the change it created a new zone in AD which would overwrite the other zone. Usually if you change one then the other you will get a pop up message that says the zone already exists in AD and asks if you want to use the zone in AD or overwrite the existing zone. If the change was made before the zone replicated it may have overwritten the other zone. Win2k3 will create conflicting zones in AD giving one a name beginning with CNF. I don't think Win2k does this, it just overwrites it. I've seen this behavior myself on my two DCs before I figured out I just had to wait for replication.
