Hi i have a massive directory containing the home directories, all permissions are screwy and what i effectively want to do is set the permissions for each home dir (obviously not allowing inheritable permissions) then the objects contained within that directory to inherit them. the problem is if i enable policy inheritance it gives it to the home drive itself making it insecure and if i dont then if i drill down a few dirs and it doesnt touch them.

any help would be greatly appreciated.

You could do this:

1. Knock out all permissions at the parent directory and all subdirectories.
2. Seize ownership of the parent directory and all subdirectories.
3. Give full access to domain admins and "System" account at the parent directory level, and turn on inheritance.
4. Run this command while inside the parent directory:
for /d %a in (*.*) do cacls %a /t /e /g %a:F

This command assumes that the folder names are identical to the account names and that the folder names contain no embedded spaces.

I note that your Subject line reads "xcacls". You can, of course, use that command too but you will need to resolve its syntax rules.
