[setup:  
Win2K Pro SP4  
512MB RAM  
763 MB page file]

Has anyone had this problem: A normal explorer window on your Win2K system will hang over a very minor "cause"—like you're just clicking on a window's title bar to move the window, or you're clicking on the minimize|restore button in the upper rt corner of window? I mean, what I've got happening is that once or twice an evening, the window(s) visible on the monitor will hang up bigtime when I'm doing something trivial like the above, & the only way to get things right is to bring up Task Mgr and stop the task associated w/ the frozen window(s). A couple of times when it's happened, I've had the presence of mind afterward to go into Event Mgr and look for "X's", but there's never any sign in the Application or System log that points to anything specific going wrong. Another thing: Invariably when the hangup happens, there's plenty of RAM available on the machine. Does any of this ring a bell with you Win2K experts out there? I'd appreciate very much hearing any credible theories. Thanks for your time & attention to detail!
