Hi all,

I have a network of approximately 50 users and have enable roaming profiles for all users.

One problem I am experiencing is that when a user logs on to more than one machine simultaneously this causes problems in regards to their data being backed up/restored.

Im know this is happening because of the fact that the one user has 2 sessions open on 2 different at the same time therefore when it comes to backing up/restore this causes a mix up.

I have asked many of my contacts in the IT field (IT Professionals, Teachers and Friends etc)

I want to know how one goes about configuring Windows server OS so that it prevents users logging on simultaneously on different workstations.

I remember when I was studying at college Novell Netware would prevent simultaneously logins because if the user was already logged onto a workstation and attempted to log on to another machine the user would be prompt with a message similar to the following:

"You are currently logged on to another workstation, please ensure that you're logged off on any other machines and try again"

Thanks in advance.

Regards,
Steven
