Hi

I'm working on building an ASP.NET application that integrates with Quickbooks. I need my application to launch quickbooks and do what it has to do. I've not written any ascripts to change the registry before.

The COM object will need to have the launch and access permissions modified to include ASPNET and INTERACTIVE. The launch and access permissions are in binary in the registry. I've started reading a book by jerry honeycutt but it doesn't show how to append something like ASPNET to a binary without deleting the existing permissions. How I can append ASPNET and INTERACTIVE to the access and launch permissions? A sample script would be very helpful

Thanks
Harry
