Lets see...

1. You don't have a firewall and connected to the internet without an antivirus scanner installed..
2. You have not updated your version of windows in a very long time (if you had, the patch to stop the worm you are infected with would have been installed).
3. You don't have much contact with the outside world. Blaster and Sasser are two of the most highly publicized worms to ever be released, yet you have no idea that you have at least one of them on your machine.

Your lack of computer security practices has resulted in your computer being infected with the SASSER worm. I would venture to guess that your machine is also infested with spyware, adware, malware and a host of other worms and viruses.

Until you can at least practice a modicum of computer security, such as having a firewall and UPDATED antivirus program installed, and keeping windows updated with the latest critical patches, you should not connect to the internet. Your poor judgment and unsafe practices make you a threat to anyone in your address book, and the rest of the internet (your machine is most likely spreading the worm as you read this).

If you are not a troll, and I suspect you are, you need to educate yourself on basic computer security.

Bobby
