Well, to clear things up, I'm not as confused as before.

Now, I'm still trying to figure out, how to physically getting rid of the two drivers I downloaded via Windows update. The problems arose just then.

Every time, I put in my USB BT dongle, the drivers sitting somewhere in Windows are detected for that device. This is what I was trying - deleting the sys files in System32 dir and removing all registry entries. Deleting the files seemed to restore the sys files immediately, which was/is really strange. I also want to get rid of the Bluetooth entry in the system control panel, which I also couldn't get done. So I also tried to delete the CPL for the control panel entry.

But I was actually just trying. I'm a little desperate on this as you can see.

So, after all this crap, system restore really looks like an option. Though I'd like to avoid it somehow, but I need a better way, maybe a tool to do it for me.

Is safe mode of any good there?

Karsten

Thanks for the alerting me, Peter. I do think twice before posting answers.

Could you please let me know the mistake that I did in the earlier post ?
