Thanks for the reply – tried the netbios thing on the Linksys and no change. Thanks anyway

Ok, maybe I wasn't as clear as some of you wanted. I will try to explain exactly where we are at.

Location A

One Server running Server 2003 w/DNS/DHCP/AD  
Broadband connection through modem to Linksys BEFSX41  
domain – locationa.local – not associated in any way with any other  
domain or office  
internal subnet 192.168.2.0  
40 workstations running XP Pro  
VPN has been established with Location B via BEFSX41 Router

Location B

One Server running Server 2003 w/DNS/DHCP/AD  
Broadband connection through modem to Linksys BEFSX41  
domain – locationb.local – not associated in any way with any other  
domain or office  
internal subnet 192.168.1.0  
40 workstations running XP Pro  
VPN has been established with Location B via BEFSX41 Router

>From Location A

>From either server or workstation when going to network neighborhood/entire network/microsoft network we only see the locationa domain and when clicking on that all workstations and server are visible. Pull up windows explorer and type in known IP address of another workstation at location b (when doing search for computers) that workstation is able to be viewed and files transferred back and forth. When going into command prompt and pinging any known ip's for workstations at location b, ping is successful.

On server at location A, attempted to open active directory trusts, right clicked on domain locationa.local and select properties then trust and attempted to add locationb.local domain and message said

that domain could not be found

At this point, all what we would like to do (with what we have as stated in the setup above) is that when a user at either location a or b goes into network neighborhood, they will be able to view the other domain and access the systems (granted they have the correct username/password/permissions)

Thanks again

.
