Hi Nightowl,

I appreciate your reply and glad to inform you that its worked fine even in domain environment. I again pleasure to convey my thanks.

Though it might looks unimportant for any readers, your reply is much useful when we get in trouble or problems while we adding a user in multiple groups. Your command worked successfully for domain users also.

I just given as you mentioned in your reply as the user is domain user and when i noticed in user accounts it taken that name as a domain user and successfully added.

Thanks again. By the way, may i get your personal email id so i will mail you any other doubts as in future if i post anything here in the forum, it might be unseen by you.

Thanks again.

Regards
Chandra

Hi chandra

Yes, I think I understand.

The quickest way to add a user to several groups, if you don't want to use Local Users and Groups, is to open a command window and use the net localgroup command.

```
net localgroup "power users" MarkBouch /add  
net localgroup Debuggers MarkBouch /add
```

You can create the user account in the first place this way, too:

Re: add user in more than one group through user accounts in control panel

Re: add user in more than one group through user accounts in control panel

```
net user [username] [password] /add /active:yes
```

Unless you have a security policy in place that forbids this, Power Users can manage local groups, so your users could add themselves to Debuggers this way without you having to log in as admin and do it for them. However, I think in your first post you said they also needed to be members of the Administrators group? If that's so, that's something they can't do themselves; only an admin has that power.

Having said all that though, it may still be necessary for the user to log off and on again for the account changes to become active. I'm not on a domain here so I can't check. I'm sorry I can't help more, but I'm not an expert on this -- perhaps someone else may be able to help more.
