I got it.

It's in the file: C:\windows\Debug\NetSetup.LOG

thx

Hello,

Anyone knows a way to identify the Domain Controller which was used to join a computer to the domain?

In IP ranges that are undefined in Sites and Services (or due to other infrastructure problems), a computer that wants to join the domain, finds the most available DC.

Where on the computer itself can I find the DC that was used to join the domain?

In our environment there are 30+ DCs, I don't want to check each one of them.

Thx

Wieger
