Winguy-

you are just spouting off a bunch of BS to me. i said nothing about safe mode or sfc. did you even read my post? you are not talking to a dumbass

here. i was hoping an advanced user like myself would shed some light on my problem, not tell me about proper backups, xp cd's or anything else. FYI- the emergency repair procedure i referred to in my first post is a documented procedure in microsofts KB. i have done this procedure many times before with success. I always use it as a last resort. the emergency repair procedure is basically a manual system restore performed from the recovery console.

now this problem i get when i do this seems to only happen when I work on dell's, compaqs, gateways, etc... my guess is that it has something to do with their disk duplication methods stripping the sids, like sysprep does.
