Hi everybody,

This is driving me crazy as I cannot get it to work.

Here is the situation:

We have a DSL connection shared with the whole network (5 boxes)

No IP addresses on any of the machines.

All machines are connected to the hub, which has the modem/router (siemens SpeedStream 5200) connected to it as well.

So any machine (xp at least) I plug in the hub automatically are connected to the web.

One of the machines (XP Pro) has a modem which I configured to receive connections from a dialup member of the network.

Any machines dialing in will gain access to the network just by supplying the given password, but I cannot figure how to share the existing DSL connection with the dialup user.

I remember that by having two or more network adapters will display a "sharing" tab on the network properties, but I'm not sure this is the way out, because the user is connecting to the network through a dialup modem, not a network card.

Can it be done at all?

If so, how can I configure it?

Thanks a lot for your attention.

Eder Wainer
